INTRODUCTION

- Healthcare systems are **complex adaptive systems** consisting of interacting agents that act autonomously, respond to their environment, and influence one another in dynamic, often unpredictable ways.^{1,2}
- Implementing **complex health technologies** requires systemic changes in care delivery, coordination, and infrastructure.
- Traditional HTA** approaches often assume linear, isolated effects and fail to capture feedback, resource constraints, and emergent system behaviour.^{3,4}
- Systems-level modelling** (e.g., discrete event simulation, system dynamics, agents-based modelling) can represent these interactions, asses operational feasibility, and support more realistic implementation planning.

OBJECTIVE

To synthesise how **systems-level modelling** is applied to evaluate and support implementation of **complex health technologies** within healthcare delivery systems.

- We define **complex health technologies** as interventions that may be complex in their design or in their implementation, requiring adaption of existing processes for effective use (e.g., cell and gene therapies, AI-assisted diagnostics, or digital health systems)
- This review aims to:
 - Classify model types and application contexts
 - Assess complexity using the SIMULATE framework (System, Interaction, Multilevel, Understanding, Loops, Time, Emergence).⁵
 - Examine model limitations and whether models informed real-world decisions or remained conceptual.

METHOD

- Systematic searches were conducted in **Web of Science, Embase, MEDLINE (Ovid), and CINAHL (EBSCO)** covering **2000-2025**.
- The **search** strategy combined terms for: *simulation and modelling methods + health technologies and interventions + healthcare context*.
- Searches retrieved **5,542 records** after duplicates were removed.
- Screening and selection follow **PRISMA** principles using **ASReview** for semi-automated title/abstract screening.⁶
- Screening is **ongoing: 30 studies currently included for full text**.

PRELIMINARY RESULTS

30 empirical studies included to date, screening ongoing.

Fig 1. Relationship between model type, context level, and technology domain (n=30)

Technology Domain

- ATMP (Advanced Therapies)
- Care Delivery & Clinical Pathways
- Diagnostics & Genomics
- Emergency & Resilience
- Telehealth & Remote Monitoring
- Health IT & Operations
- Robotics & Automation
- Supply Chain & Immunisation Operations
- General / Unspecified

Included studies

- Reynolds et al. (2022) – Dispensing robots
- Abou-Hamad & Arisha (2013) – General
- Abou-Hamad & Arisha (2017) – General
- Aeenparast et al. (2013) – General
- Ajdari et al. (2018) – General
- Abbas et al. (2023) – Smart Insufflation Technique
- Caglayan et al. (2022) – mAb Infusion Therapy
- Chalk et al. (2019) – Bladder Cancer Pathway
- Gorelova et al. (2024) – Remote Monitoring System
- Bhosekar et al. (2021) – Automated Guided Vehicles
- Abir et al. (2024) – Hospital Evacuation Planning
- Aboueljinane et al. (2014) – EMS System
- Huguet et al. (2022) – Tele Consultations
- Becker et al. (2019) – Tele ICU
- Blake et al. (2023) – Cold Stored Platelets
- Aboueljinane & Frichi (2022) – EMS System
- Aboueljinane et al. (2022) – EMS System
- Asgary et al. (2021) – Mass Vaccination Site
- Bozzani et al. (2021) – General
- Lam et al. (2021) – CAR T-Cell Therapy
- Tully et al. (2019) – CAR T-Cell Therapy
- van de Ven et al. (2022) – Whole Genome Sequencing
- Erasto et al. (2025) – Blood Drone Delivery
- Brailsford & Da Silva (2015) – Dentistry
- Fanta & Pretorius (2023) – Digital Health System
- Wang et al. (2023) – CAR T-Cell Therapy
- Tseng et al. (2024) – CAR T-Cell Therapy
- Badré et al. (2020) – Patient Assignment System
- Miller et al. (2022) – Robotic Rehabilitation
- Wang et al. (2019) – CAR T-Cell Therapy

Hybrid models:
DES/ABM (18, 22); SD/ABM (27); DES/Mixed Integer Linear Programming (23); DES/Simulation Optimisation (16, 17); Fuzzy Logic/Reinforcement Learning (11)

Other models:
Mixed-Integer Nonlinear Programming (29), Stochastic Multiscale Model (30)

Fig 2. Level of application per model type

Application level

- Conceptual/prototype (hypothetical data)
- Real-world data, no decision support
- Decision support (pre-implementation)
- Implemented once
- Institutionalised/iterative use

Table 1. Overview of main simulation approaches applied in healthcare. Adapted from sources^{4,7-9} and included studies.

Model	Intended purpose	Advantages	Disadvantages	Example
Discrete Event Simulation (DES)	DES analyses individual-level processes and queues; resource use; discrete event for optimisation, prediction, and comparison.	Captures heterogeneity and time-varying attributes; good for operational and queueing problems, flexible and updatable.	Data- and time-intensive; programming and calibration can be heavy.	10 Bhosekar et al. (2021) developed a <i>DES</i> + optimisation framework to redesign a hospital's automated material-handling system, improving the efficiency of surgical case delivery using automated guided vehicles.
Agent Based Model (ABM)	ABM focuses on agents with local rules; interactions, learning, and emergent behaviours in adaptive systems.	Captures relationship networks; fits public health and infrastructure planning; handles deterministic and stochastic processes; tests behavioural responses.	Data-hungry; long build and calibration time; coding burden.	25 Fanta & Pretorius (2023) built an <i>SD</i> model to examine sociotechnical feedback loops in digital-health implementation, linking technology acceptance, information quality and user satisfaction in Ethiopian hospitals.
System Dynamics (SD)	SD analyses system-level stocks, flows, delays, and feedback; simulates behaviour over time (qualitative or quantitative).	Reveals feedbacks and emergent behaviour; suited for nonlinear, complex systems; has been used to test and compare policy and management interventions.	Limited individual-level detail; validation often qualitative if data is weak.	26 Wang et al. (2023) applied <i>ABM</i> within a simulation of CAR T-cell therapy logistics to represent interacting hospitals, manufacturing sites, and couriers.
Hybrid Model	Hybrid models combine methods when one is insufficient; integrates levels and subsystems for complex decisions.	Leverages complementary strengths; improves realism and validity; allows best-fit method per subsystem; supports learning and decision-making.	Higher model complexity; extra effort to link methods; harder verification and validation across modules.	22 Van de Ven et al. (2022) combined <i>DES</i> and <i>ABM</i> to support nationwide implementation of whole genome sequencing for lung-cancer care.

ONGOING ANALYSIS

- Full-text screening and data extraction are ongoing for remaining studies
- Comparative analysis focuses on:
 - Complexity** of technologies: how definitions of ‘complex’ or ‘disruptive’ vary across studies.
 - SIMULATE-coverage**: whether models address all complexity dimensions or emphasise selected elements.
 - Model limitations**: how authors document constraints, assumptions, or validation challenges.
 - Model evaluation**: whether hybrid models are more often implemented or updated over time.
- Findings will inform recommendations on how to model complex health technology implementation more systematically and transparently.
