Background

- Breast cancer is the most common cancer in women and second overall in Norway 1 Hormone receptor positive (HR+) breast cancer, the most common form of breast cancer in Norway, is generally treated with endocrine therapy 2,3
- Abemaciclib was approved by the European Medicines Agency (EMA) in 2018 for HR+, HER2- (human epidermal receptor 2 negative) locally advanced/metastatic breast cancer in combination with endocrine therapies. In 2022, EMA approved the early breast cancer indication for abemaciclib based on monarchE trial.
- Lilly's monarchE phase 3 trial investigated abemaciclib in combination with endocrine therapy as treatment for HR+, HER2-node-positive, high risk, early breast cancer and has demonstrated improvement in invasive disease free survival 4

Figure 1. EBC Patient population and groups

Female patients with HR+, HER2-Stage I-IIIC breast canc that received surgery Diagnosed between 2010-2019

Cohort 1 (C1) high risk (in monarchE)

Low/moderate risk

Objective

To assess the percent and demographic and clinical characteristics of female patients in Norway with early breast cancer (EBC) with high-risk of disease recurrence, who met the high-risk criteria in monarchE (cohort 1), a Ph3 trial of abemaciclib for the adjuvant treatment of HR+, HER2-, node-positive, high-risk, early breast cancer

Study Design/Methods

Methods:

High risk

Low/moderate

risk

- Observational retrospective study: data from the national Norwegian Breast Cancer Register
- Statistical analysis: descriptive statistics and survival rate estimated using Kaplan-Meier curve

Clinical characteristics

Exclusion criteria: breast cancer diagnosis at autopsy

Patients meeting monarchE trial (cohort 1) criteria for high risk of recurrence: having ≥4 ipsilateral axillary lymph nodes or 1–3 ipsilateral axillary lymph nodes and grade 3 and/or primary tumor size ≥5cm.

Patients not meeting monarchE trial (cohort 1) criteria for high risk of recurrence were classified as patients with low/moderate risk of disease recurrence.

Results

Size of populations and demographic characteristics

Total population=20,632 patients

Figure 2. Size of patient groups

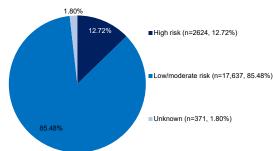

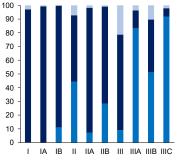

Table 1. Diagnosed cases per year and age at diagnosis

Figure 3. Breast cancer stage

■High risk ■low/moderate risk ■Unknown

Figure 4. Number of positive lymph nodes at surgery

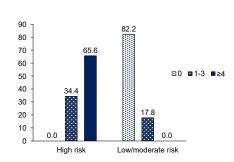

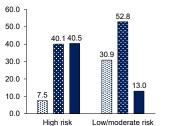

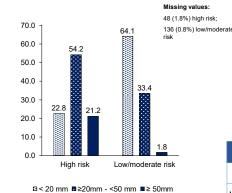

Figure 7. 5-years overall survival

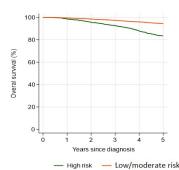

Figure 5. Tumor grade

Missing values: 15 (0.6%) high risk, 76 (0.4%) low/moderate risk Unknown grade: 298 (11.4%) high risk, 493 (2.8%) low/moderate risk

5-years survival (%) (95%CI) 83.49 High risk 94.34 Low/moderate risk (93.83 - 94.81)

Conclusions

- > A total of 20,632 HR+, HER2- early breast cancer female patients were diagnosed in Norway between 2010 and 2019. 2,624 (12.7%) of them met the inclusion criteria for cohort 1 high risk of recurrence used in the monarchE trial and are likely to benefit from novel treatment strategies targeted for patients with a high risk of disease recurrence
- > monarchE-like high-risk population accounted for most stage III cancers and presented increased tumor size. All cohort 1 high risk patients had at least one positive lymph node at surgery, while a high percentage of the low/moderate risk population did not show any positive lymph node (82.18%). No patients in not-high risk population had LN ≥ 4.
- The 5-year overall survival rate was significantly lower in the monarchE-like cohort 1 high risk population compared to the low/moderate risk population (83.49% vs 94.34%; p<0.0001).
