### Background

- In Colombia in 2013, melanoma was still a rare tumour, being diagnosel in approximately 4.5100,000 individuals per year. Unfortunately, its case-fatality was relatively high, making melanoma a nuch more fatal cancer here than in the high indicence areas of the world.
   Comparatively, in Colombia in 2020, the 5-year prevalence of melanoma diagnosed among men and women was 5268, reflecting an increased annual incidence of 10.351/00,000 individuals.<sup>2</sup>
- The treatment landscape for advanced, non resectable melanoma has transformed over the last decade with the development and approval of non-chemotherapy systemic treatments including immune checkpoint inhibitors (I-O therapies) and targeted therapies (BRAF inhibitors), mitogen-activated protein kinase (MEK) inhibitors).<sup>2</sup>
- Despite recent advances in long-term overall survival (OS) in some populations, long-term, quality survival remains elusive for many patients.
- quarty so that termine usate on matching potential. Results from the 78-month data of the CheckMate 067 trial showed that NIV0-IPI had significantly longer progression-free survival (PFS) (HR = 0.79 (95%C), 0.64-0.96)) and a non-tratticically significant improvement for OS (HR = 0.83 (95%C), 0.67-1.03) versus NIV0-49 Results from this trial have also showed that the combination regimen has similar efficacy errors enring in choroure
- cross patient subgro Given the addition of NIVO monotherapy and the NIVO-IPI combination regimen to the varie of existing treatments available for patients with advanced melanoma, it is important synthesize the available evidence across all treatments and evaluate the cost-effectiveness these regimens.

### Objective

The objective of this study is to evaluate the cost-effectiveness of NIVO and NIVO+IPI versus pembrolizumab (PEM), and dabrafemib+trametinib (DAB+TRAM) in the first-line treatment of patients with advanced melanoma from the Colombian payer perspective.

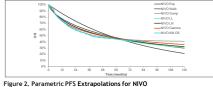

### Methods

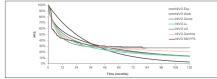

### Model Structure

- A three-state partitioned survival model was developed which considered time-varying hazard ratios to estimate costs, life-years (LYS), and quality-adjusted LYS (QALYS) over a 30-year time horizon.
- The competing treatments considered in the analysis included NIVO, NIVO+IPI, PEM, and DAB+TRAM.

Costs and health outcomes were discounted at 5% annually, to align with Instituto de Evaluación Tecnológica en Salud (IETS) guidelines.<sup>6</sup>

#### Figure 1. Parametric OS Extrapolations for NIVO

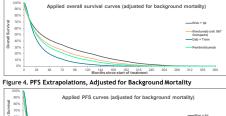

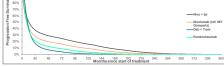

#### Survival Projections

Survival projections for all competing treatments were estimated based on the relative treatment effects estimated in the NMA, which are represented by time-varying HRs relative to NIVO

- For both OS and PFS, it was found that HRs significantly changed over time for key comparators included in the analysis, so an NMA that could capture these variations was considered more appropriate than an NMA considering constant HR.
- The NIVO reference survival curves were estimated via parametric survival analysis of the DeckMate 067 Soard PF3 Zhennth data. Based on Aukke information criterion (AIC) and Bayesian information criterion (BIC) statistical estimations of goodness of fit, abserved fit, and the appropriateness of the underlying hazard, the Compertic distribution was deemed the best fit based on the 78-month data analysis (Figure 1 and Figure 2).
- The time-varying relative treatment effects for OS and PFS were applied to the NIVO reference survival curves until the end of the observed data included in the NMA.
- The OS and PFS estimates produced by the model are presented in Figure 3 and Figure 4, respectively. These projections include Colombia-specific age-adjusted background mortality, and the treatment effects estimated in the NMA.

### Figure 3. OS Extrapolations, Adjusted for Background Mortality

- Drug Acquisition and Administration Costs
   Treatment-specific drug acquisition and administration costs per month were based on the
   number of treatment cycles per month, dosage per administration, and cost per package. The
   dosage required for infusion therapies was estimated using the mean patient mass of 66 kg.<sup>1</sup>
   Treatment costs for infusion-based therapies were rounded up to the nearest vial required to
   account for wastage. A 3 mg/kg dose was used for NIVO in both monotherapy and for
   maintenance when in combination with IPI.
   Exe. induced dures down administration cost.
- maintenance when in combination with in. For infusion drugs, administration costs included general chemotherapy infusion administration costs (COL5634,700 per session). Oral drugs were assumed to have a monthly administration cost of zero.
- Treatment durations for NIVO and NIVO-IPI were directly estimated using the 78-month follow-up time-to-treatment discontinuation (TTD) data from the Checkmate 067 study. Due to the lack of available data, it was assumed that PEM TTD was equivalent to that of NIVO. For PD-1 agents (NIVO, NIVO-IPI, PEM) a 2-year stopping rule was applied to the trial-
- observed TTD curve. A treat to progression with a maximum duration approach was applied to DAB+TRAM, as median treatment durations are generally aligned with the PFS shape of the extrapolations for BRAF+MEK combination therapy.

Presented at ISPOR Europe 2023; November 12-15, 2023; Copenhagen, Denmar

#### Subsequent Treatment Costs

- After progression following first-line treatment, it was assumed that, for each comparator, a proportion of patients received second-line treatment.
- Subsequent therapy post-progression was based on a distribution of subsequent treatments, including the option for no treatment. In the base case, the distribution of therapy received was based on BRAF mutation status-specific distributions estimated by clinical experts in Colombia. These BRAF-specific distributions were then weighted by the proportion of the population
- that is BRAF wild type (WT) (70%) and BRAF mutant (30%),9 to allow for an all-comer analysis (Table 1).
- (1able 1). The mean cost of subsequent therapy was calculated from the monthly cost of treatment and the duration of subsequent therapy (assumed 21 weeks duration based on PFS from Zimmer 2017;<sup>61</sup> IPI was assumed a fixed duration of 10.5 weeks based on Checkmate 067). The cost, proportion, and duration were weighted together to estimate a mean cost of follow-up reatment per month

### Table 1. Subsequent Treatment Distribution

	Initial Therapy					
Subsequent Therapy	NIVO	NIVO+IPI	PEM	DAB+TRAM *		
NIVO		6%	16%	9.2%		
IPI			-	27.3%		
VEM	25%	15%	25%	19.3%		
DAB	25%	15%	25%			
DAB+TRAM	14%	11%	14%			
PEM	16%	14%	16%			

Source: Colombian clinical expert opinion; \* Robert et al., (2019).<sup>11</sup> Note: Weishted average of distributions for RPAE mutant and WT patients based on expert opini

#### **Disease Management Costs**

- Disease management costs included healthcare encounters outside of regularly sch administration encounters, assigned on the basis of progression status (pre/post) and treatment status (on/off) (Table 2).
- One time event costs at the time of progression and death were also applied.
- Monthly and one-time event costs were derived from resource use estimates informed by key opinion leaders (KOLs). Unit costs were based on 2022 list prices.<sup>12</sup>

#### Table 2. Disease Management Costs

Category	Cost Per Month (COL\$)
Pre-progression - On treatment	1,624,270
Pre-progression - Off treatment	1,119,266
Post-progression - On treatment	1,791,688
Post-progression - Off treatment	1,791,688
Disease progression (one time cost)	3,339,248
Death (one time cost)	948

- The frequency of grade 3/4 adverse events (AEs) by treatment was included as inputs to more fully capture the impact on cost and quality of life associated with being on treatment. Frequencies of AEs were based on the clinical trials. 40.0
- The costs for grade 3/4 AEs were assumed to be equivalent to the hospitalization costs asso with that event (*i.e.*, a grade 3/4 AE will result in hospitalization). Costs were obtained fro Manual Tarifario SOAT de Salud (2022) from Colombia (Table 3).<sup>12</sup>

#### Table 3. Adverse Event Costs and Utility Decrements

Adverse Event	Cost Per Event (COL\$)	Utility Decrement
Abdominal pain	3,500,000	-0.130
Atrial fibrillation	4,500,000	-0.170
Autoimmune colitis	5,600,000	-0.170
Autoimmune hepatitis	5,600,000	-0.170
Autoimmune thyroiditis	4,500,000	-0.170
Colitis	5,600,000	-0.170
Dehydration	5,600,000	-0.130
Diabetic ketoacidosis	12,000,000	-0.170
Diarrhea	5,600,000	-0.130
Enterocolitis	7,500,000	-0.170
Febrile neutropenia	16,500,000	-0.170
Guillain-Barré syndrome	120,000,000	-0.170
Malabsorption	12,500,000	-0.170
Myocardial infarction	65,000,000	-0.170
Pancreatitis	45,000,000	-0.170
Pulmonary embolism	45,000,000	-0.170
Pneumonia	35,000,000	-0.170
Respiratory failure	45,000,000	-0.170
Syncope	15,000,000	-0.170
Upper abdominal pain	5,500,000	-0.130
Vomiting	3,500,000	-0.130

#### Health-Related Quality of Life

- Vality analysis based on EQ-50 data collection in the CheckMate 067 trial (78-month follow-up) was used in the model using United Kingdom tariffs (Colombian-specific tariffs were not available), in alignment with Colombian IETS guidelines.<sup>4</sup> Utilities were estimated for the progression-free and post-progression health states, via longitudinal regression adjusting for baseline utility observed in the trial, time until death (Table 4).
- Differences in the regression coefficient for the assigned treatment arm were assumed to be associated with differential toxicity. The NIVO treatment arm was applied as the reference case
- associated with dimensional to the minor dimension of the event, and these were explicit. Additional AE decrements were assigned for each event, regardless of which treatment triggered the event, and these were weighted by the treatment specific and line-specific frequency of the event, and these were weighted by the treatment specific and line-specific frequency of the event. events to derive a treatment-specific toxicity decrement while patients remained on treatment (Table 3).<sup>14</sup>

#### Table 4. Utility Weights

Health State	Utility
Pre-progression	0.807
Post-progression	0.782
Month prior to death	-0.374

#### Sensitivity Analyses

- Dne-way sensitivity analyses were performed on model parameters including utility inputs, discount rates, disease management costs, and AE costs for the ICUR of NIVO vs. DAB-TRAM, NIVO vs. PEM, NIVO-PI vs. DAB-TRAM, and NIVO-PIT vs. PEM. Additional scamations were conducted to examine the impact of assumptions on time horizon (20 years), survival assumptions (use independently fit parametric survival curves from CheckMate 067 for NIVO-PI nal NIVO), and subsequent treatment (no active treatment assumed). Probabilistic sensitivity analysis was also conducted.

### Results

E

## Base Case

- ssociated with cost savings (COL\$2,457,700,118 and COL\$69,259,660), higher LYs (3.33 vs. 2.28 and 3.01), and higher QALYs (2.62 vs. 1.76 and 2.36) compared to DAB+TRAM and PEM, respectively (Table 5)
- Fight, Fight, Linker, Linke
- CULS2.503.137.471.
  INVOIPI was the cost-effective treatment option compared to PEM, with an incremental cost-utility ratio (ICUR) of CULS3.866.610 per QALY, falling below the cost-effectiveness threshold of COLS2.7000,000 per QALY (equivalent of 1 x GDP per capita in Colombia) with incremental costs of COLS3.303.021.

### Table 5. Base Case Results

#### Sensitivity Analysis

- Across all one-way sensitivity analyses for NIVO vs. DAB+TRAM, NIVO vs. PEM, and NIVO+IPI vs. DAB+TRAM, the results showed NIVO-based therapy to be the dominant treatment option.
- The top 7 parameters to which the ICUR was most sensitive in one-way sensitivity analysis are presented in Figure 5 for NIVO-IPI vs. PEM. The ICUR was most sensitive to changes in the utility values and discount rates; however, all ICURs fell below the COLS27,000,000/QALY cost-effectiveness threshold, and NIVO-IPI remained the cost-effective treatment option.
- In scenario analyses, the model results were robust and aligned with those in the base case
- To understand the impact of the uncertainty in the model, probabilistic sensitivity analysis was conducted performing 1,000 replications of the model. The results are presented on an incremental cost-effectiveness plane (Figure 6 and Figure 7) and showed the robustness of the base case results.

- Discussion and Limitations The availability of long-term data, including survival and treatment duration, has allowed the survival extrapolation to be precisely estimated. Estimations of the reference OS and PFS curves for nivolumab were based on CheckMate 0b7 data with 78 months of follow-up. The best fitting parametric distributions were selected based on statistical metrics of goodness-of-fit, visual inspection of the extrapolated curves, and plausibility of the combined expressions of OS and PFS within a given treatment arm. White several distributions provided similar fits to the observed data, there was considerable variability in the extrapolated tails. This is not uncommon given the difference docuts by treatment arm shifted, the incremental estimates for NiVO and NiVO-IP vs. comparators included in the analysis, so an NAM that could capture here variations was considered and across treatments, it was found that. His significantly changed over time for key comparators included in the analysis, so an NAM that could capture these variations was considered here appropriate than an NAM considering more appropriate NIVO and NIVO-IP vs. comparators included in the analysis, so an NAM that could capture NIVO and FUM are expected to be similar given their similar molecular makeng, survival projections for PEA are potentially underestimated due to the IP arm in Keynote-06 reporting higher OS than the IP arm in the CheckMate 067 study (as the link between PEA to the network depends on the comparison to IP).

### Conclusion

NIVO and NIVO+IPI are the cost-effective and dominant treatment options compared to DAB+TRAM and PEM for the first-line treatment of advanced melanoma patients in Colombia
